

## Substructure Determination using SHELX

SHELXD: From *Ab initio* to substructure solution  
 Phasing and Density Modification with SHELXE  
 ARCIMBOLDO

Isabel Usón, ICREA, IBMB-CSIC, Barcelona  
 uson@ibmb.csic.es

## Crystallographic Phase problem

$$\rho_{xyz} = (1/V) \sum_{hkl} F_{hkl} \exp[-2\pi i (hx+ky+lz)]$$

## Soft X-rays for experimental phasing

## SHELXD + SHELXE George Sheldrick

- SHELXD: to determine a heavy atom or anomalous scatterer substructure from  $\Delta F$  or MAD  $F_A$  data.
- SHELXE: once the substructure is known, it can be used to calculate reference phases, and from them phases for the whole structure but usually, density modification is required

## Ab Initio: Phasing by Direct methods

Most small-molecule structures are solved by *direct methods*. Approximate phases for the strongest reflections are derived from the measured intensities

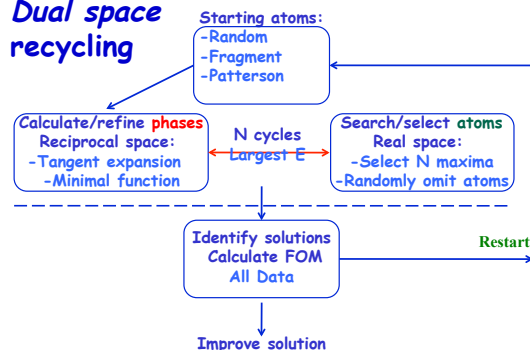

This is enough to find most atoms, and then complete the structure

Making some general assumptions, it is possible to exploit the *high redundancy* of the diffracted intensities: (100 independent reflections / atom)

Equal atom structures with > 200 atoms are a problem

## Dual space recycling

Shake & Bake // SHELXD  
 Sheldrick, Hauptman, Weeks, Miller & Usón (2001), *International Tables for Crystallography Vol. F*, eds. Arnold & Rossmann, pp. 333-351

## Figures of merit: CC, PATFOM, minimal function, CCweak...

$$CC = \frac{[\sum W E_o^2 E_c^2 \cdot \sum W - \sum W E_o^2 \cdot \sum W E_c^2]}{\{[\sum W E_o^4 \cdot \sum W - (\sum W E_o^2)^2] \cdot [\sum W E_c^4 \cdot \sum W - (\sum W E_c^2)^2]\}^{1/2}}$$

Fujinaga & Read. (1987). *J. Appl. Cryst.*, 20, 517-521.

## Structures solved by SHELXD

Compound	Spacegroup	N(+solv)	HA	dÅ
Actinomycin X2	P1	273(305)	-	0.9
Actinomycin Z3	P2 <sub>1</sub> 2 <sub>1</sub> 2 <sub>1</sub>	186(307)	2Cl	0.96
Vancomycin	P4 <sub>3</sub> 2 <sub>1</sub> 2	202(312)	6Cl	1.09
Actinomycin D	P1	270(314)	-	0.94
Ristocetin A	P2 <sub>1</sub>	294(420)	-	1.03
Hirustasin	P4 <sub>3</sub> 2 <sub>1</sub> 2	402(467)	10S	1.2
Cyclodextrin	P2 <sub>1</sub>	448(467)	-	0.88
Decaplanin	P2 <sub>1</sub>	448(635)	4Cl	1.00
Cyclodextrin	P1	483(562)	-	1.00
Bucandin	C2	516(634)	10S	1.05
Amilose CA26	P1	572(719)	-	1.1
Viscotoxin B2	P2 <sub>1</sub> 2 <sub>1</sub> 2 <sub>1</sub>	722(812)	12S	1.05
Mersacidin	P3 <sub>2</sub>	750(826)	24S	1.04
rc-WT CvHiPIP	P2 <sub>1</sub> 2 <sub>1</sub> 2 <sub>1</sub>	1264(1599)	8Fe	1.2
Cytochrome c3	P3 <sub>1</sub>	2024(2208)	8Fe	1.2

Triclinic Lysozyme, biggest equal atom structure.

## Experimental phasing of macromolecules

Find the small molecule in the macromolecule:

heavy atoms provide reference phases

calculate the phases  $\phi_T$  of the full structure by:

$$\phi_T = \phi_A + \alpha$$

$\phi_A$  is the calculated phase of the heavy atom substructure

$\alpha$  can be estimated from the experimental data

The phase determination requires the following stages:

1. Location of the heavy atoms.
2. (Refinement of heavy atoms and) calculation of  $\phi_A$ .
3. Calculation of starting protein phases using  $\phi_T = \phi_A + \alpha$ .
4. Improvement of these phases by density modification.

## Substructures of heavy atoms and anomalous scatterers

If  $|F_P| \gg |F_A|$ , adding  $\alpha = 90^\circ$  to the phase of  $|F_A|$  gives a good approximation to the phase of  $|F_T|$ .

## Substructure solution with SHELXD

Protein	#sites	kDa	SG	d <sub>min</sub>	CC	P ratio
ApD	3/3 Se	16	C222 <sub>1</sub>	2.2	45	16
RRF	3/4 Se	20	P4 <sub>3</sub> 2 <sub>1</sub> 2	4.0	60	1.4
ModE	6/6 Se	57	P2 <sub>1</sub> 2 <sub>1</sub> 2	3.0	66	7.3
9hem	18/18 Fe	64	P2 <sub>1</sub>	2.9	73	4.0
AT	32/32 Se	160	C2	3.5	49	5.1
Cyanase	40/40 Se	170	P1	2.4	57	1.0
TH	51/60 Se	161	P2 <sub>1</sub>	2.5	52	2.8
AEP	66/66 Se	270	P2 <sub>1</sub>	2.55	61	13
KPHMT	145/160 Se	567	P2 <sub>1</sub>	2.8	49	35

- Anomalous scatterers were traditionally found with Patterson or Direct Methods.
- SHELXD solve larger substructures combining Patterson, direct methods and geometry.

- ### SAD phasing procedure in SHELXE
1. Calculate *centroid phases* ( $\alpha = 90$  or  $270^\circ$ ) with weights that depend on the (normalized)  $|\Delta F|$ .
  2. Use these phases, foms and  $|F_T|$  to calculate a map, apply *low density elimination* (Woolfson, Giacovazzo) and reinvert map to estimate phases for small  $|\Delta F|$  and centrics. This is an alternative to B.C.Wang's method of solvent flattening to *resolve two-fold ambiguities*.
  3. If heavy atoms are present in the native, include their  $\sigma_A$ -weighted direct estimates of  $\phi_T$  (as in the heavy-atom method for small molecules, does not use  $|\Delta F|$ ).
- These three steps produce independent phase estimates (2 and 3 are orthogonal to 1) so can be combined using  $\sigma_A$ - weights (Read).

### Maps with no/a free lunch

Best experimental phases after den. mod. (MapCC 0.57)

After expansion to 1.0 Å with virtual data (MapCC 0.94)

### Autotracing in SHELXE

352aa protein 1.6Å, Anna Larsson, A. Jones, Uppsala

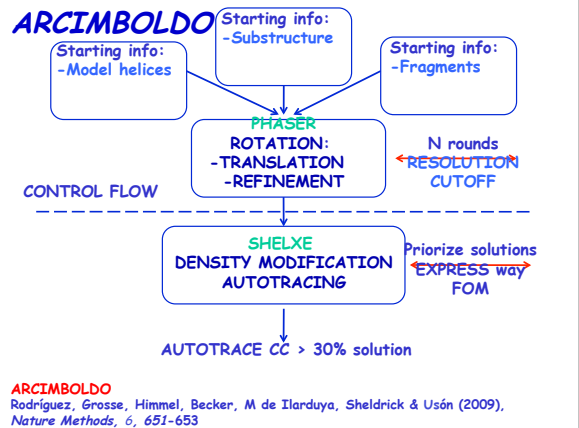

### ARCIMBOLDO: fragments rather than atomicity

<http://chango.ibmb.csic.es/ARCIMBOLDO>

• **ARCIMBOLDO**: combines fragment search (PHASER, Read), experimental phasing, density modification, auto tracing (SHELXE, Sheldrick), within a multisolution frame. (2.0 Å)

• Condor Grid

**ARCIMBOLDO**  
Rodriguez, Grosse, Himmel, Becker, M de Ilarduya, Sheldrick & Usón (2009), *Nature Methods*, 6, 651-653

### Hell D (Andrea Thorn)

- up to 8 copies of a 30 aa peptide with 3 disulfide bridges, I422
- 1.95Å Data collected at 1.9Å, 2Xtals
- Substructure could not be located (difficult even with calculated data...)
- Can be solved with ARCIMBOLDO with 2 helices from related structures
- Partial solution can be completed with anomalous signal

### Viscotoxin A1, Aritra Pal

- P4<sub>3</sub>2<sub>1</sub>2 in House Data, 1.54Å, 1.3Å
- locate substructure against anomalous data with Phaser (six cysteines in three S-S bridges)
- Expand and autotrace

### Torture Case: Gordon Leonard's DNA

- 8 base-pairs in  $P6_1$ : 14 P, data to 2.4 Å
- Can we solve it from the atoms? MPE = 70°
- From the anomalous data? MPE = 40°
- Can we find the substructure at 2.4 Å from calculated data and phase the structure?  
MPE = 33°
- At 2.8Å? NO substructure
