

Inhomogeneity →

"Perfect" crystals

Crystal-scale phenomena, e.g. twinning
(diffraction-based techniques
are more suitable)

"Homogenous" rocks

Fracture-dominated
behaviour

"Heterogenous" rocks

Inclusion-dominated
behaviour (e.g. porosity, inclusions)

What are geomaterials, why do they matter?
What do we want to measure?
Image analysis for discrete materials
Conclusions

Quantitative imaging
Key properties in "continuum materials"
A quick overview on key segmentation techniques

How do we define this threshold?

- "by eye" → NOT quantitative....and user dependent. (The study of its evolution *can* still be quantitative if consistent.)
- *a-priori information* such as the total porosity (I still get its distribution!)
- Categorizing thresholding methods (local+global)
 - Histogram shape-based methods
 - Clustering-based methods (e.g. Otsu, which minimizes the intra-class variance)
 - Entropy-based methods
 - Object Attribute-based methods
 - ...

edge detection
(e.g. variance).

(a) Grey scale image

(b) Segmented aggregate labelled image

The Pandora's box of segmentation....which one to use?

- Histogram-based methods
- Edge detection
- Watershed transformation
- Level set methods
- Trainable segmentation
- Region-growing methods
- Compression-based methods
- Clustering methods
- Dual clustering method
- Partial differential equation-based methods
-

3personal take: any method is a-priori fine, as long as one is aware of the induced error and is able to quantify it using ground-truth reference cases.

Continuum

e.g. granite,
basalt, marble...

Discrete

e.g. sand,
powders, clay...
